used to estimate how NTD programmes might be affected by interruption of interventions and the remedial strategies that could be implemented once programmes resumed. The models suggested that the impact on some NTDs could ultimately be mitigated, provided the delay was minimal and that prompt remedial (and in some cases novel) action was taken.^{2, 3}

The effect of programme interruptions on the dynamics of 7 NTDs (soil-transmitted helminthiasis, schistoso-a [LiggÆina d\LivalLiggÆbWcWfVLiggÆftWca UÆ visceral leishmaniasis [VL] in the Indian sub-continent and the form of human African trypanosomiasis [HAT]) was analysed by simulating each disease in different endemic settings. The transmission dynamics of each NTD and the level of endemicity at each glu [Vig] b] Lival [Vig] b] Lival [Vig] [Vig]

Initial modelling (in March 2020) suggested that, if the impact of COVID-19 on NTD services was as substantial as 1 to 2 years of cessation of interventions (e.g. annual A DAAMA dU[bgAbXAMj YAMYADX]b[AbXATYLIa YbhE for VL and HAT), it could in some cases delay achievement of elimination goals for longer than the duration of the interruption. For schistosomiasis, onchocerciasis, trachoma and visceral leishmaniasis, the mean delay due to a 1-year interruption was predicted to be 2–3 years in the areas of highest prevalence. Modelling suggested that delays could be mitigated by additional A DAAEfABb\UbWAAWY \(\tilde{D}X\) \(\tild

The WHO

8 shows that the number of people who received JblMfj YblJcbgÆ[UbglÆBHDgÆY`Æ][bJÚMbhnÆVYlk YbÆ 2019 and 2020, with a small recovery in 2021. Fewer rounds of MDA were implemented overall than before the pandemic, and several MDA rounds did not achieve their target coverage. While 250 MDA campaigns were implemented in 83 countries in 2019, only 180 campaigns were implemented in 72 countries in 2020, a decrease of 28%. In 2021, the number of MDA campaigns was 187 in 66 countries, a slight increase over 2020.9 Major disruptions were also observed in health-facility services for NTDs, such as prevention, treatment and care.

Fewer cases of diseases that require individual management (e.g. VL, HAT and leprosy) were detected and treated in 2020 than in 2019. Although decreasing trends in the detection of new cases had been observed for some of these diseases for several years, it is unclear whether the greater reduction in the numbers detected and treated in 2020 was real or is attributable to disruptions in active and passive case detection due to movement restrictions for both health staff and patients, resulting in fewer services and worse health-seeking VY\U |ci f.ÆN\YÆLHYÆZÆYgi f|YbWÆZÆBZWhjcbgÆgÆNZÚ cult to estimate, as the actual rate of new infections is predicted to increase once active case detection is resumed.⁹ For example, the sharp decrease in the bi a VYfÆZÆNU bcgYgÆZÆYdfcgmÆbÆBfUh]Æ [[YghgÆNUhÆ a number of cases were undetected, also in other areas. 10 It may take some time for the impact of COVID-19 on NTDs to be fully understood, with different impacts in different settings, depending on the public health response.

Impact of COVID-19 on interruption of vaccinepreventable diseases

The COVID-19 pandemic disrupted the delivery of YggYbl]UA[a a i b]rLl]cbAgYfj]WgAEbXAXYUYXAEUMJbU tion campaigns and the roll-out of COVID-19 vaccines when they became available. Estimates of national la a i b]rLl]cbAybj YfU YAZCa AK HCAEbXAE B=CEFAZCfAE 2021 indicated substantial decreases in the coverage of YggYbl]UA[a a i b]rLl]cbAgYUlj YAECAZO19¹¹ An estimated 25 million children were un- or under-vaccinated against diphtheria, pertussis and tetanus (DTP) in 2021, 6 million more than in 2019 and the highest number g]bWAZCO8AEZAEYgY,AEbAgy]a UYXABAE] ``]cbAgYYAEYffC dose" children, who had not received a single dose of

Accuracy of malaria control disruption and extension modelling during the COVID, tive st texten0 9.i &e £159 1418 £051ndo se£7.ic, 14148 241/10 Dv6285/AHvr(0519 141/10 14

supply chains for critical commodities, including antimalarials and diagnostics, and that the treatment-seeking behaviour of febrile individuals might change or health facilities become overburdened. To better understand these concerns, WHO engaged several malaria modelling groups to estimate the impact of different scenarios. Now that the initial waves of COVID-19 have passed, the modelled estimates can be compared with what transpired.

Models of the potential impact of severely disrupted or totally interrupted mass LLIN distribution campaigns indicated that a 50% reduction in delivery would result in over 18 million additional malaria cases globally in 2020²² and that totally interrupted LLIN campaigns with interrupted SMC would result in approximately 300 000 additional deaths from malaria in sub-Saharan Africa.²³ Most countries, however, maintained LLIN distribution campaigns, with 74% of the nets scheduled for distribution globally in 2020 distributed.²⁴ SMC was provided in all 13 West African countries in which it was planned, and indoor insecticide spraying was completed in 25 of the 37 countries for which it was intended.⁶

chaînes d'approvisionnement pour les produits essentiels, notamment les médicaments antipaludiques et les produits de diagnostic, une baisse de la propension des personnes fébriles à se faire soigner ou une surcharge des établissements de santé. Pour mieux comprendre ces préoccupations, l'OMS a fait appel à plusieurs groupes de modélisation du paludisme pour estimer l'impact de différents scénarios. Les premièresTw 9.5 0 0 9.5 293.4

The modelled impact of disruptions to diagnosis and hfYUra YbhAEUgAg[b]ÚWbhAEbAEbYAghi XmABAEUgAgg]a UYXXE that a 75% reduction in diagnosis and treatment would result in a 13% increase in malaria incidence.4 In another study, it was estimated that complete suspenglcbÆZÆFYUha YbhÆbXÆYU bcglgÆcfÆkYÆFghÆGÆ cbhkgÆ of COVID-19 would result in an additional 164000 deaths from malaria per year.⁵ Many fewer tests for malaria were conducted in 2020 than in 2019, perhaps due to changes in treatment-seeking behaviour and the availability of diagnostics.6 The number of cases of malaria reported globally increased between 2019 and 2021, with an estimated 13.4 million cases and 63 000 deaths attributed to service disruptions due to COVID-19.25 Because of poor-quality data on both interventions delivered and malaria cases detected, however, |hAgan|ZÚW/hAfcanyhnfa|byAfsyAfadUwwezaenfi|Wan|gfidtions on the malaria burden in more detail, as different impacts were observed in different settings. The outputs of modelling were used by global malaria lbj Ygl [Urfg Ar Ara d\UgnYAr Ya dcfhbW. Zar UblUbing malaria control interventions, and many national malaria programmes used the outputs to justify continuing planned interventions. Even though the worst-case scenarios considered by modellers did not transpire, the outputs provided a valuable tool for advocacy to highlight the potentially devastating situation and to join malaria stakeholders in a common aim.

Conclusions and recommendations

The ITFDE underscores the need for caution in interpreting the impact of the COVID-19 pandemic.
Modelled estimates often provide "worst-case scenarios" for advocacy and planning. The ITFDE recommends that 26uommep.mvgali7r (nds th04,d in)23 (t)5 (e)-9 (r)iuat49.9 se
